
The Internet: Philosophy & Technology

Scott Bradner
Harvard University
Feb 4 2002

hw 2/4/02 - 1

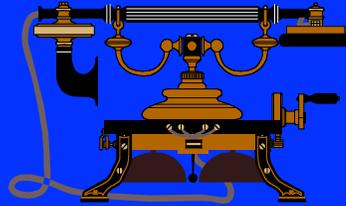

The Network That Was There

- ◆ **the** Phone Net from The Phone Company (TPC)
- ◆ circuit-based
 - assumed simple & predictable interconnections between hosts
 - assumed requirement for QoS
 - assumption of being carrier-provided
 - voice-oriented

hw 2/4/02 - 2

Traditional Phone Network

- ◆ circuits & “smart network”
- ◆ connection-oriented
- ◆ hard state in network devices
- ◆ fragile
- ◆ central resource control
- ◆ socialist? "for the good of all"
- ◆ applications in network
 - e.g., phone switch
 - end-to-end touch-tone signaling was a mistake
- ◆ predictable development path
 - extended development cycle

bu 2/4/02 -3

What Was Wrong With That?

- ◆ nothing, if you just wanted to talk
- ◆ nothing, if you just wanted to talk to Joe
- ◆ nothing, if you just wanted one service
- ◆ nothing, if you thought innovation had stopped
- ◆ nothing, if you thought that AT&T innovated
- ◆ nothing, if you wanted your data service provided to the wall by a carrier
 - (ISDN is the answer, what was your question?)

bu 2/4/02 -4

So, Lets Make (Not Build) our own

- ◆ multiple unrelated efforts (early to mid 1960' s)
 - packet switching theory: (Kleinrock) 1961
 - day dreaming: (Licklider' s Galactic Network) 1962
 - make use of remote expensive computers: (Roberts) 1964
 - survivable infrastructure for voice and data: (Baron) 1964
- ◆ ARPANET (late 1960' s)
 - Roberts ARPANET paper 1967
 - RFP for "Interface Message Processor" won by BBN 1968
 - four ARPANET hosts by 1969
 - public demo and email in 1972

hw 2/4/02 - 5

Fundamental Goal of Internet Protocols

- ◆ multiplexed utilization of **existing** networks
 - different administrative boundaries
 - multiplexing via packets
 - networks interconnected with packet switches
 - called gateways (now called routers)
 - note: international in scope
- ◆ did not want to build a new global network
 - too expensive
 - too limiting

hw 2/4/02 - 6

Internet Protocols Design Philosophy

- ◆ ordered set of 2nd-level goals
 - 1/ **survivability** in the face of failure
 - 2/ support **multiple types** of communications service
 - 3/ accommodate a **variety** of network types
 - 4/ permit **distributed management** of resources
 - 5/ **cost effective**
 - 6/ **low effort** to attach a host
 - 7/ **account** for use of resources
- ◆ note: no performance (QoS) or security goals
- ◆ not all goals have been met
 - management & accounting functions are limited

hw 2/4/02 - 7

Packets!

- ◆ basic decision: use packets not circuits
 - Kleinrock's work showed packet switching to be a more efficient switching method
- ◆ packet (a.k.a. datagram)

Dest Addr	Src Addr	payload
-----------	----------	---------

 - self contained
 - handled independently of preceding or following packets
 - contains destination and source **internetwork** address
 - may** contain processing hints (e.g. QoS tag)
 - no delivery guarantees**
 - net may drop, duplicate, or deliver out of order
 - reliability (where needed) is done at higher levels
 - no authentication of packet header**

hw 2/4/02 - 8

Routing

- ◆ sub parts of the network are connected together by computers that forward packets toward destination
these computers are called “**routers**”
- ◆ routers use destination address in packet to make forwarding decision
- ◆ routers exchange reachability information with other routers to build tables of “next hops” toward specific local networks
exchange of reachability information done with “**routing protocol**”

hw 2/4/02 - 9

A Quote

*“the lesson of the Internet is that **efficiency is not the primary consideration**. Ability to grow and adapt to changing requirements is the primary consideration. This makes simplicity and uniformity very precious indeed.”*

Bob Braden

hw 2/4/02 - 10

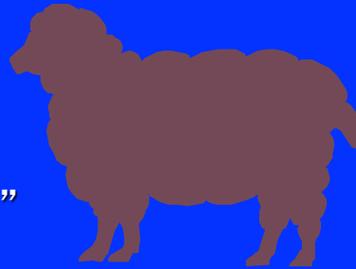

End-to-End Argument

- ◆ 1981 paper by Saltzer, Reed & Clark
- ◆ “smart networks” do not help
 - adding functions into network can be redundant since actual function is **end-to-end**
 - e.g. encryption, data reliability
 - also harder to change to support new technology
 - also see Lampson *Hints for Computer System Design*
- ◆ e2e argument projected to mean
 - no per-session knowledge or state in the network
 - but some “soft-state” (auto refreshed) may be OK
 - network should be transparent to end-to-end applications

hw 2/4/02 - 11

Internet

- ◆ packets & e2e
- ◆ soft state in network devices
- ◆ resilient
- ◆ competitive resource control
- ◆ capitalist? "individual initiative"
 - but too much selfishness hurts all
 - must play by the same rules - but no enforcement
 - the tragedy of the commons**
- ◆ applications in hosts at edges (end-to-end)
 - and in 3rd party servers anywhere on the net
- ◆ hard to predict developments
 - chaos at the rate of “Internet time”

hw 2/4/02 - 12

Smart vs. Stupid Networks

- ◆ phone network technology: self-named “Intelligent Network” (IN)
 - many network-based services
 - admission control, number translation, accounting, ...
- ◆ Isenberg’s *Rise of the Stupid Network* compared phone network’s “Intelligent Network” to Internet
 - Isenberg’s basic messages:
 - network (i.e. carrier) -based services slow to change
 - voice is not all there is
 - carrier gets in the way
 - just “deliver the bits” works

bn 2/4/02 - 13

But!!

- ◆ a “stupid network” is a commodity service
 - the price of a commodity service is driven by the stupidest vendor
- ◆ hard to make money delivering commodity services
- ◆ new network infrastructure is very expensive
 - fiber optic cables (with installation) & hardware
- ◆ access rights can also be very expensive
 - e.g. wireless spectrum licenses
- ◆ carriers need something else to make money
 - common dream is that services or content will save the day
 - may be a false dream (other than porno)

bn 2/4/02 - 14

But!! (2)

- ◆ packets w/o circuits cause problems
 - can not do guaranteed QoS
 - can not control path packets take
 - can not reserve capacity for application
 - security control harder
 - do not have logical “wire” back to source
 - management harder
 - can not see data patterns on the network
 - finding non-catastrophic failures harder
 - service provider interconnections harder
 - no clean interface for problems
- ◆ lack of useful formal tools to describe performance

!QoS

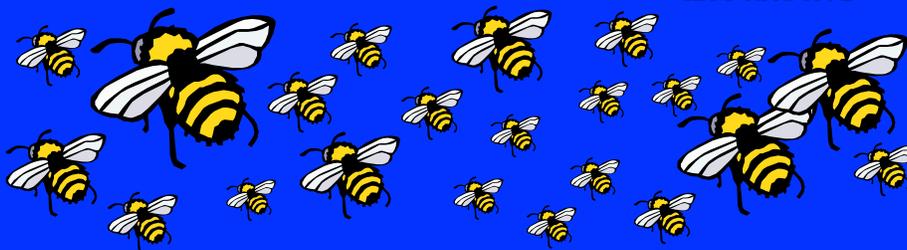

bu 2/4/02 - 15

Conceptualization Problem

- ◆ fundamental disconnect between “Internet” and “phone” people “bell-heads vs. net-heads”
- ◆ by their definition the Internet can not work and must be fixed - they will rescue us

“You can not build corporate network out of TCP/IP.”

IBM circa 1992

bu 2/4/02 - 16

More Conceptualization Problems

- ◆ service provided by 3rd parties - not only by carriers

different from phone world

- ◆ a quote from an IETF telephony mailing list

Hi Roy,

I still don't understand why it is a "users" choice where the "services" are executed - I would have thought that this would be networks choice

bn 2/4/02 - 17

IP as a Common Bearer Service

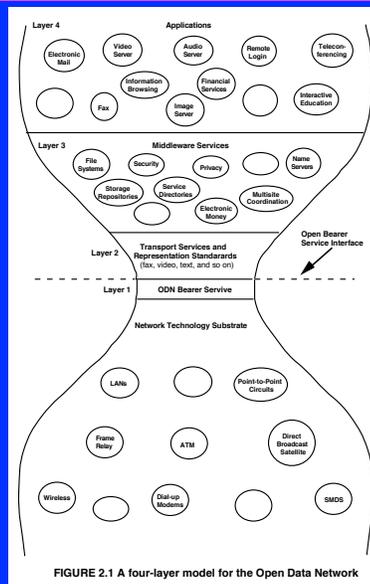

FIGURE 2.1 A four-layer model for the Open Data Network

From: Realizing the Information Future

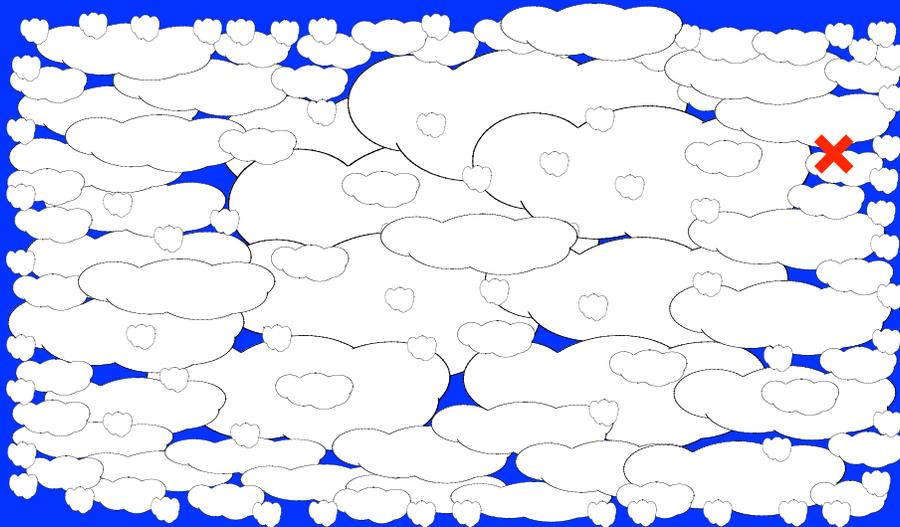

bn 2/4/02 - 18

Trust-Free Environment

- ◆ original Internet architecture assumed a trustworthy environment
- ◆ no longer the case
 - mistrust net itself (eavesdropping, reliability etc)
 - mistrust that you are talking to the right end point
 - e.g., proxy, redirect, spoofing (MAC & IP address)
 - unsolicited correspondence (spam)
 - anonymity hard to get
 - mistrust own hardware and software
 - 3rd parties insist on being in the middle
 - filters, wiretapping, ...

hw 2/4/02 - 19

Current Internet Architecture

✗ you are here

hw 2/4/02 - 20

Numbers and Names

- ◆ nodes on IP networks have addresses
 - currently addresses are 32-bit values (IPv4)
 - total possible addresses: 4,294,967,295
 - written as 4 short numbers separated by periods
 - e.g., 128.103.60.212
 - IPv6 uses 128-bit addresses
 - total possible addresses:
340,282,366,920,938,463,463,374,607,431,768,211,456
- ◆ half of IPv4 addresses have been assigned
 - address assignments are conservative these days
 - IPv6 developed to deal with shortage

hw 2/4/02 - 21

Uniqueness of Addresses

- ◆ addresses have to be unique within scope
 - scope = connected network - e.g., the Internet
 - since address used to direct packet to destination
- ◆ can have address translators (NAT) if not unique
 - but NATs hurt end-to-end model
- ◆ blocks of addresses assigned by regional IP address registries
 - each with a unique geographic scope
 - competition is not appropriate when trying to conserve a scarce resource

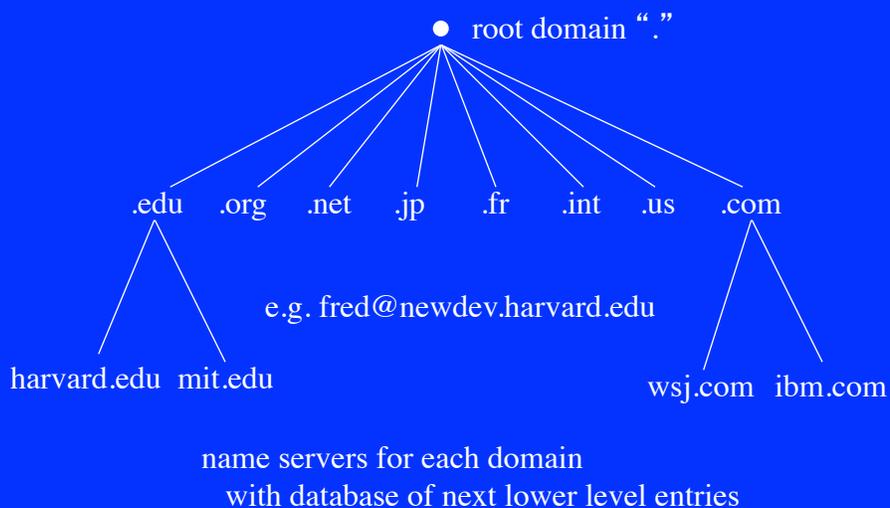

hw 2/4/02 - 22

Names for Addresses

- ◆ addresses change and are hard to remember
 - addresses change when networks are reconfigured
- ◆ service can be provided from more than one computer
 - for load distribution and/or reliability
- ◆ started with centrally maintained table that people downloaded
 - but that quickly became too big to stay accurate
- ◆ Domain Name System (DNS) developed to allow distributed database for mapping

bu 2/4/02 -23

Domain Names

bu 2/4/02 -24

Uniqueness of Names

- ◆ single DNS tree required to ensure consistency
 - if >1 root then if you & I look something up we may get different responses if using different roots
- ◆ some proposals for >1 root
 - motivated by desire to not have single control point
 - but no technical way to ensure consistency

hw 2/4/02 - 25

Standards

- ◆ a common (standard) transport is needed for interoperability
 - IP is the common bearer service for the Internet
- ◆ a common (standard) congestion control mechanism is needed to keep the net from collapsing
 - TCP & SCTP are the IETF congestion control protocols
- ◆ common application technology needed within each application for interoperability
 - e.g., email, www
 - counterproductive to prohibit alternates: innovation is good

hw 2/4/02 - 26

Coordination

- ◆ uniqueness is a requirement in a number of things
 - addresses
 - names
 - protocol parameters
- ◆ unique things have to be coordinated
 - i.e., one authoritative database
- ◆ ICANN coordinates some Internet things: “IANA”
 - continuing work of Jon Postel
 - addresses & dns top-level domains
 - protocol parameters from the IETF

hw 2/4/02 - 27

Limited Standardization

- ◆ IETF (and others) create “standards” for the Internet
- ◆ but use of the Internet not restricted to these “standards”
- ◆ can be an issue when a company refuses to open technology (or to support a standard)
 - e.g., instant messaging

hw 2/4/02 - 28

Signing Stuff

digital signatures

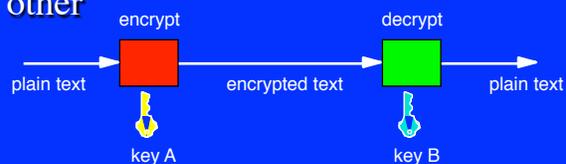

hw 2/4/02 - 29

Encryption

- ◆ symmetric (shared secret) system
same key used to encrypt and decrypt

- ◆ asymmetric (public key) system
separate keys for encryption and decryption
data encrypted by one key can only be decrypted by the other

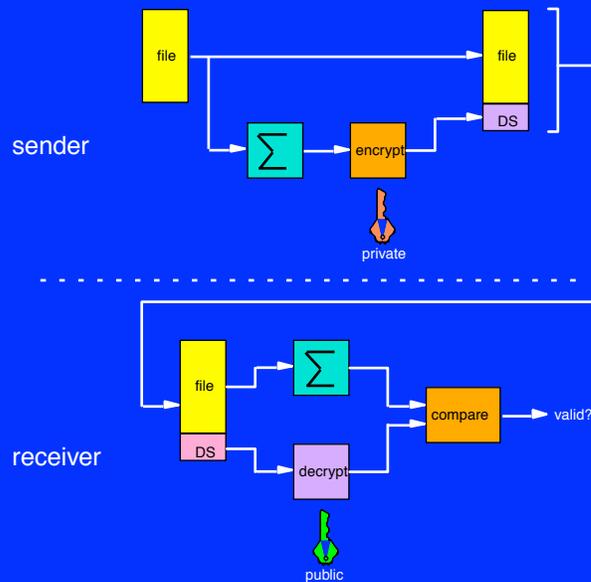

hw 2/4/02 - 30

Digital Signature

- ◆ need method to be sure that message came from *A* and was not changed
 - use *Digital Signature*
 - appended to message before sending
- ◆ procedure for using a digital signature
 - A* computes a one-way hash function of the contents of the message
 - A* encrypts hash code with its private key the result is appended to the message
 - when it gets the message *B* computes the same hash function on the body of the message
 - B* then decrypts the received hash code using *A*'s public key
 - if the hash codes match, the message came from *A* and the contents were not altered in transmission

hw 2/4/02 - 31

Digital Signature contd.

hw 2/4/02 - 32

Digital Signatures

- ◆ data integrity
 - ensure that the data did not change since DS created
- ◆ data origin authentication
 - only person with knowledge of private key can create DS
 - so I can be sure you created it
- ◆ non-repudiation of origin
 - different way to say data origin authentication
 - I can show that it must have been you who created DS
 - unless you can show that your private key was compromised

hw 2/4/02 - 33

Public Keys

- ◆ I need to find out your public key to send you a secure message
- ◆ you need to find out my public key to authenticate a message from me
- ◆ need to get key in a secure, non-forgable way

hw 2/4/02 - 34

Certificates

- ◆ public key with digital signature(s)
 - can have more than one digital signatures
- ◆ “signed” by someone or some organization you trust - personal knowledge vs. certificate authority
- ◆ X.509 is ISO standard for certificates
 - x.509 v3 adds DNS name & loosens hierarchy requirements

hw 2/4/02 - 35

Certificate Issues

- ◆ revoking certificates
 - certificate revocation list (CRL)
- ◆ expiration date & renewal process
- ◆ is a signed document “legal”?

hw 2/4/02 - 36

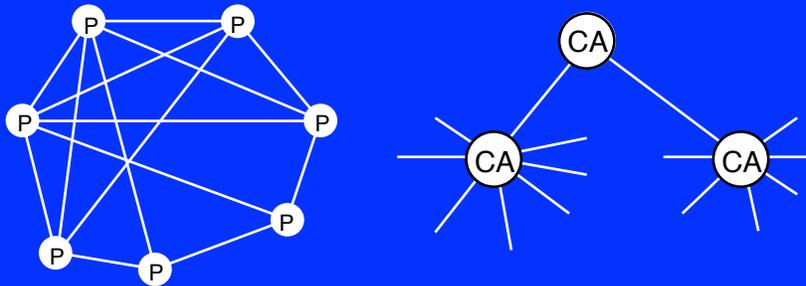

Web-of-Trust Vs. PKI

- ◆ web-of-trust

 - you send me certificate signed by someone I know

- ◆ PKI

 - hierarchical infrastructure of certificate authorities
 - chain of trust

hw 2/4/02 - 37

PKI Issues

- ◆ a PKI would be good except

 - need system that covers all relevant users

 - corporate-wide for corporate applications

 - world-wide for general Internet commerce

 - liability issues: what could CA be liable for?

 - privacy issues: identity assurance - how about anonymity?

 - jurisdictional relationships: what laws to follow?

 - local CA procedures: what identity assurance was used?

- ◆ will not happen soon

hw 2/4/02 - 38
